Any questions on the previous material?

We have covered:

- Brief background and examples of natural selection
- dN/dS as a tool to measure the action of natural selection, explained using the first counting method for estimating dN/dS (Nei-Gojobori, 1986) and its extensions
- Next section: Codon substitution models the basis of modern (1998-) dN/dS estimation approaches

Codon-substitution models

- In 1994, first tractable mechanistic evolutionary models for codon sequences were proposed by **Muse and Gaut** (MG94), and, independently, by **Goldman and Yang** (GY94) [in the same issue of MBE, back to back]
- Markov models of codon substitution provide a powerful framework for estimating substitution rates from coding sequence data, as they
 - encode our mechanistic understanding of the evolutionary process,
 - enable one to compute the phylogenetic likelihood,
 - permit hypothesis testing or Bayesian inference,
 - systematically account for confounding processes (unequal base frequencies, nucleotide substitution biases, etc.),
 - afford many opportunities for extension and refinement (still happening today).

A likelihood approach for comparing synonymous and nonsynonymous nucleotide substitution rates, with application to the chloroplast genome

S. V. Muse and B. S. Gaut Mol Biol Evol 11 715-724 (1994)

~1000 citations

A codon-based model of nucleotide substitution for proteincoding DNA sequences.

N. Goldman and Z. Yang
